Antioxidant and alpha-glucosidase inhibitory activities of 
Euchresta horsfieldii

Abstract. Prihantini AI, Krisnawati, Setyayudi A. 2019. Antioxidant and alpha-glucosidase inhibitory activities of Euchresta horsfieldii. Biofarmasi J Nat Prod Biochem 17: 61-64. Euchresta horsfieldii, known as pranajiwa, is a medicinal plant that is widely grown in Bali and West Nusa Tenggara, Indonesia. Its seeds or fruits are commonly used for body freshness and stamina. The present study aimed to investigate the biological activities of leaves, root, stem, fruits, seeds of the E. horsfieldii. Antioxidant, alpha-glucosidase inhibitory activities and total phenolic compound were evaluated from methanolic extracts of all parts of E. horsfieldii. The result showed that leaf extract of E. horsfieldii exhibited the highest antioxidant activity with IC50 215.11±8.06 µg/mL. Meanwhile, the root extract had the highest alpha-glucosidase inhibitory activity and total phenolic compound with IC50 29.76±13.17 µg/mL and 763±0.01 mg GAE/100mg dry extract, respectively. In conclusion, the study suggested that E. horsfieldii is potential as natural source of antioxidant and alpha-glucosidase inhibitor agents.

Keywords: Alpha-glucosidase inhibitor, antioxidant, Euchresta horsfieldii, total phenolic content

INTRODUCTION

Free radicals, the chemical compounds having one or more unpaired electrons, play a critical role in our health. They are highly unstable and can damage other molecules by extracting electron in order to attain stability. Reactive oxygen species (ROS), the free radical generated from oxygen, initiate bimolecular oxidation and affect resultant DNA damage, protein carbonylation, and lipid peroxidation which leads to cell death and creates oxidative stress such as cancer, cardiovascular disease, neurological disorder, arthritis, atherosclerosis as well as aging process (Khalaf et al. 2007; Pham-Huy et al. 2008; Chanda and Dave 2009; Piao et al. 2009). Antioxidants can help our body to deal with oxidative stress caused by free radical-induced damage.

The high accumulation of ROS can also enhance the risk of diabetes (Ha et al. 2008; Noh and Ha 2011). Diabetes mellitus is a condition defined by the level of hyperglycemia. Some reports suggested that decreasing the level of postprandial hyperglycemia is one of most effective therapeutic approaches in the early period of diabetes mellitus (Lee et al. 2009; Ghadyale et al. 2011; Van de Laar et al. 2012). Other studies demonstrated that alpha-glucosidase inhibitors helped to control postprandial blood glucose levels in diabetic patients (Sancheiti et al. 2011; Gurudeeban et al. 2012).

Our nature is rich in potential compounds for drugs or medicines. A medicinal plant in Indonesia known as pranajiwa (Euchresta horsfieldii) grows in forest and is categorized as a threatened plant (Moge et al. 2001). Its seeds and fruits have been traditionally used for stimulants, aphrodisiac, refreshments, asthma, tuberculosis, cough, hyperlipidemia, etc. (Heyne 1987; Kloppenburgh 2006; Tirta et al. 2010; Kim et al. 2011). The seeds and fruits are produced as traditional herbal drink called jamu and other products with high economic value. The leaf of E. horsfieldii has been reported to have antioxidant activity and increase enzyme activity of superoxide dismutase and glutathione peroxidase in Wistar rats (Tirta et al. 2010; Gunawan et al. 2017). However, fewer reports studied on other parts the plant and alpha-glucosidase inhibition activity as an approach for diabetes management. Therefore, the aim of the study was to evaluate the bioactive compounds particularly antioxidant and alpha-glucosidase inhibitory activities from roots, stems, leaves, fruits, and seeds of E. horsfieldii. Furthermore, total phenolic content of the extracts was also evaluated since they are considered for having contribution as antioxidants or alpha-glucosidase inhibitors.

MATERIALS AND METHODS

Chemicals
Quercetin, 1,1-diphenyl-2-picrylhydrazyl (DPPH), p-nitrophenyl-α-D-glucopyranoside, and alpha-glucosidase were obtained from Wako Pure Chemical Industries Ltd., Osaka, Japan. Folin-Ciocalteu reagent was purchased from Sigma Aldrich, Japan. All the solvents used were at the highest purity available.

FREE OF CHARGED
Extract preparation

Approximately 10 g dried samples of roots, stems, leaves, fruits, and seeds of pranajiwa were extracted with distilled methanol. The extracts were filtered and concentrated under a rotary evaporator and then vacuum dried. The extraction was conducted twice to obtain approximately 1 g crude extract.

DPPH radical scavenging activity assay

The DPPH radical scavenging activity was conducted based on a previous method (Jayaprakash et al. 2001) with minor modifications. Various concentrations at 20, 50, 100, and 200 μg/mL of samples were mixed with 0.5 mL of the 1 mM DPPH radical solution in methanol. A similar solution without a sample was used as control. Absorbance was measured using a UV-vis spectrophotometer at 517 nm after incubation at room temperature under dark condition for 30 min. Quercetin was used as a positive standard. The percentage of scavenging activity was determined by the following formula:

\[
\text{Scavenging activity (\%)} = \left( \frac{A_{\text{sample}} - A_{\text{control}}}{A_{\text{control}}} \right) \times 100\%
\]

Alpha-glucosidase inhibition assay

The alpha-glucosidase inhibitory activity of the crude extracts was evaluated using a method described by Dewi et al. (2014). The reaction mixture containing 5 μL of the sample was dissolved in DMSO at various concentrations and 495 μL of 100 mM phosphate buffer (pH 7.0) was added to 250 μL of 3 mM substrate solution p-nitrophenyl-α-D-glucopyranoside (PNPG). The mixtures were pre-incubated for 5 min at 37°C and 250 μL of alpha-glucosidase (0.065 unit/mL) was added to start the reaction. The incubation was continued for 15 min and the reaction was terminated by the addition of 1 mL of 0.1 M sodium carbonate. Alpha-glucosidase inhibitory activity was quantified by measuring the released product of p-nitrophenol at 400 nm. Quercetin was used as a positive standard.

Total phenolic content

The total phenolic content (TPC) of the extracts was determined using Folin-Ciocalteu reagent (Singleton et al. 1999). Approximately 500 μL of the extracts (1.0 mg/mL) was added with distilled water, made up to 8 mL, and then mixed with 500 μL of 2 N Folin-Ciocalteu reagents. The mixture was allowed to stand for 8 min and 1.5 mL of 20% sodium carbonate was then added. The reaction mixture was incubated at room temperature for 2 h. Absorbance was measured at 765 nm and the phenolic content was determined using a calibration curve obtained from gallic acid.

Statistical analysis

All assays were performed in triplicates and the data were expressed as the mean ± standard deviation. Statistical analysis was carried out using SPSS version 16.0 for Windows followed by Tukey’s post hoc test. Differences at P < 0.05 were considered to be significant.

RESULTS AND DISCUSSION

DPPH radical scavenging activity

DPPH is a stable radical widely used to evaluate the activity on scavenging free radicals. Free radicals were reduced by antioxidants that donate their hydrogen (El-Haci et al. 2013). Therefore, DPPH radical scavenging assay is common method for antioxidant evaluation. The antioxidant activity was measured by the discoloration to yellow as a stable molecule 2,2-diphenyl-1-hydrazine formed from purple solution as DPPH radicals in methanol. Activity on scavenging DPPH radical of the extracts of pranajiwa is shown in Figure 1. The activity is in dose-dependent manner and it is shown as an IC₅₀ value reflecting the required concentration for 50% inhibition. A lower IC₅₀ value represented higher antioxidant activity.

Leaves extract showed the highest activity followed by roots and stem extracts with IC₅₀ 215.11±8.06, 266.18±13.17, and 302.67±26.90 μg/mL, respectively. Meanwhile, fruits and seeds extracts had lower activity with IC₅₀ 462.7±38.32 and 468.79±42.27 μg/mL, respectively. It is interesting that, other than fruits and seeds, in which Indonesian people usually consumed, the leaves revealed potency as medicinal source. These results were supported by Sari et al. (2015), who reported that n-hexane leaves extract of pranajiwa had high antioxidant activity. Therefore, the antioxidant potency of its leaves can be considered for further utilization of herbal medicine.

The strength of antioxidant activity depends on the existence of various secondary metabolites (Emami et al. 2007). Some phenolic compounds, tannins, phenyl isopropanoids, lignans catechol and many others are good antioxidants (Rice-Evans et al., 1996). Several essential oils have also been studied for their antioxidant activities (36). Variation in the amounts of various non-volatile and volatile compounds can be one of the reasons causing differences in antioxidant activity of the extracts from different parts of plant (Emami et al. 2007).

**Alpha-glucosidase inhibitory activity**

The alpha-glucosidase inhibition activity can be related to the effort to search alternative medicines particularly for type 2 diabetes mellitus (DM). An approach to treat type 2 DM is by reducing blood glucose level in the body. Alpha-glucosidase is a catalyze enzyme on final digestion process of carbohydrates. The enzyme breaks down oligosaccharides and disaccharides into monosaccharides. Delaying absorption of carbohydrates is necessary for glycemic control (Cheng and Josse 2004). Inhibiting alpha-glucosidase activity retards the absorption of glucose (Ghadyale et al. 2011; Lee et al. 2009; Van de laar et al. 2005). Therefore, the inhibition of alpha-glucosidase activity can be used in diabetic management.

Alpha-glucosidase inhibitory activity of the extracts of pranajiwa is shown in Table 1. Roots extract had the highest activity against alpha-glucosidase followed by stems extract with IC$_{50}$ 29.76±3.76 and 107.95±4.68μg/mL, respectively. Meanwhile, leaves, fruits, and seeds extracts of pranajiwa did not show alpha-glucosidase inhibition. Roots extract, which showed high antioxidant activity and highest alpha-glucosidase inhibitory activity, revealed strong potency as natural source of anti-diabetes agent. It is due to that an ideal anti-diabetes treatment should possess both hypoglycemic and antioxidant properties (Shibano et al. 2008). It is also indicated that antioxidant assay combined with alpha-glucosidase inhibition assay is necessary for the consideration of the potencies of the plant on diabetic treatment.

**Total phenolic content**

Phenolic compounds are commonly considered to play important role in antioxidant and alpha-glucosidase inhibitory activities. Therefore, it is necessary to evaluate total phenolic content to support antioxidant and alpha-glucosidase inhibition assays. The content of phenolics was expressed in percentage of gallic acid equivalent (GAE). The evaluation of total phenolic content from various extracts of pranajiwa revealed that roots extract had the highest phenolic contents (7.63±0.01 %GAE/dry extract). On the other hand, leaves, stems, and seeds slightly lower than roots extract (7.63±0.01; 6.03±0.09; 5.89±0.01; and 4.09±0.11 %GAE/dry extract) as shown in Table 2.

Phenolic compounds can donate their electron without making themselves reactive radicals, therefore, they are considered as good antioxidant. As previous result showed that the leaves and stems had higher antioxidant activity, it implied that the antioxidant activity was contributed by their phenolic contents. It is due to the chemical structures of phenolics can stabilize unpaired electrons (Chanda and Dave 2009).

Roots extract showed the highest alpha-glucosidase inhibitory activities and higher antioxidant activity also indicating the contribution of its high phenolic content. Meanwhile, an ideal anti-diabetes treatment should possess both antioxidant and hypoglycemic properties (Shibano et al. 2008). Therefore, evaluation antioxidant combined with alpha-glucosidase inhibition assays is an approach that can be considered as a strategy for the management of diabetes. The free radicals generated from oxygen, reactive oxygen species (ROS), can cause excessive oxidation and affect diabetes (Basma et al. 2011; Meziti et al. 2012). The production of ROS increases under diabetic conditions (Noh and Ha 2011; Ha et al. 2008). Meanwhile, alpha-glucosidase inhibitors help control postprandial blood glucose levels in diabetic patients (Sancheti et al. 2011; Gurudeeban et al. 2012). It reduce the digestion and delay the absorption of carbohydrates, which relieved the postprandial increase in blood glucose levels (Cheng and Josse 2004). Therefore, roots extract of pranajiwa showed potency as source of antidiabetic agent. However, further study on isolation the active compounds is required.

On the other hand, leaves extract did not active against alpha-glucosidase enzyme, but it revealed antioxidant activity and total phenolic content slightly lower than roots extract. The result implied that the phenolics might contribute to antioxidant activity, however, less support on alpha-glucosidase inhibitory activities. It is considered that other secondary metabolites such as alkaloids and terpenes might play a role on alpha-glucosidase inhibitory activities as reported by previous study (Bahmani et al. 2014). In addition, antagonistic or synergetic interactions between secondary metabolites may have contributed to the activity (Prihantini et al. 2014; Bahmani et al. 2014).

In conclusion, leaves, roots, and stems of pranajiwa had potency for antioxidant. Furthermore, the roots had the highest activity against alpha-glucosidase enzyme and total phenolic content. The study suggested that the leaves, roots, and stems of pranajiwa had high potency as medicinal source. Therefore, overexploitation on seeds or fruits of pranajiwa can be reduced. Studies on isolation of the compounds responsible for the antioxidant and or alpha-glucosidase inhibitory activities of pranajiwa are warranted.
